Approach	How it works	Requirements and restrictions	Feasibility for your project
Steam Web API	Your website requests data from Steam's API and displays the returned information.	Your use must comply with Steam's API Terms of Use. Available data, authentication, rate limits, and applicable terms depend on the API endpoint.	**Potentially feasible.** This is the preferred approach for obtaining data through an officially documented interface.
Steam login	Users authenticate through Steam's OpenID service, allowing your website to identify their Steam accounts without collecting their Steam passwords.	Your implementation must follow Steam's authentication documentation and applicable terms. Login does not automatically grant access to every piece of a user's Steam data.	**Potentially feasible.** Useful for identifying users, but additional investigation is needed to determine whether it enables the personalization your team wants.
Web scraping	Your website automatically retrieves information from Steam's web pages rather than using an API.	Your team must evaluate applicable Steam terms and restrictions, technical limitations, and the legality of collecting and redistributing the information. Scraping may also break when Steam changes its website.	**Not recommended as the initial approach.** An officially documented API is a better starting point. Do not assume that publicly visible information is automatically unrestricted for automated collection.
